FIELD OF THE INVENTION

The present invention is in the field of medicinal chemistry and relates to compounds that are protein kinase inhibitors, compositions containing such compounds and methods of use. More particularly, this invention relates to compounds that are inhibitors of GSK-3 and Aurora-2 protein kinases. The invention also relates to methods of treating diseases associated with these protein kinases, such as diabetes, cancer and Alzheimer's disease.

BACKGROUND OF THE INVENTION

The search for new therapeutic agents has been greatly aided in recent years by better understanding of the structure of enzymes and other biomolecules associated with target diseases. One important class of enzymes that has been the subject of extensive study is the protein kinases.

Protein kinases mediate intracellular signal transduction. They do this by effecting a phosphoryl

extracellular and other stimuli cause a variety of cellular responses to occur inside the cell. Examples of such stimuli include environmental and chemical stress signals (e.g. osmotic shock, heat shock, ultraviolet radiation, bacterial endotoxin, H_2O_2), cytokines (e.g. interleukin-1 (IL-1) and tumor necrosis factor α (TNF- α)), and growth factors (e.g. granulocyte macrophage-colony-stimulating factor (GM-CSF), and fibroblast growth factor (FGF). An extracellular stimulus may effect one or more cellular responses related to cell growth, migration, differentiation, secretion of hormones, activation of transcription factors, muscle contraction, glucose metabolism, control of protein synthesis and regulation of cell cycle.

5

10

Many diseases are associated with abnormal cellular responses triggered by protein kinase-mediated events. These diseases include autoimmune diseases, inflammatory diseases, neurological and neurodegenerative diseases, cancer, cardiovascular diseases, allergies and asthma, Alzheimer's disease or hormone-related diseases. Accordingly, there has been a substantial effort in medicinal chemistry to find protein kinase inhibitors that are effective as therapeutic agents.

Aurora-2 is a serine/threonine protein kinase

that has been implicated in human cancer, such as colon,
breast and other solid tumors. This kinase is believed
to be involved in protein phosphorylation events that
regulate the cell cycle. Specifically, Aurora-2 may play
a role in controlling the accurate segregation of

chromosomes during mitosis. Misregulation of the cell
cycle can lead to cellular proliferation and other
abnormalities. In human colon cancer tissue, the aurora2 protein has been found to be overexpressed. See

et al., J. Cell Biol., 1998, 143, 1635-1646; Kimura et al., J. Biol. Chem., 1997, 272, 13766-13771.

Glycogen synthase kinase-3 (GSK-3) is a serine/threonine protein kinase comprised of α and β 5 isoforms that are each encoded by distinct genes [Coghlan et al., Chemistry & Biology, 7, 793-803 (2000); Kim and Kimmel, Curr. Opinion Genetics Dev., 10, 508-514 (2000)]. GSK-3 has been implicated in various diseases including diabetes, Alzheimer's disease, CNS disorders such as 10 manic depressive disorder and neurodegenerative diseases, and cardiomyocete hypertrophy [WO 99/65897; WO 00/38675; and Haq et al., *J. Cell Biol*. (2000) **151**, 117]. diseases may be caused by, or result in, the abnormal operation of certain cell signaling pathways in which 15 GSK-3 plays a role. GSK-3 has been found to phosphorylate and modulate the activity of a number of regulatory proteins. These proteins include glycogen synthase which is the rate limiting enzyme necessary for glycogen synthesis, the microtubule associated protein 20 Tau, the gene transcription factor β -catenin, the translation initiation factor e1F2B, as well as ATP citrate lyase, axin, heat shock factor-1, c-Jun, c-Myc, c-Myb, CREB, and CEPB α . These diverse protein targets implicate GSK-3 in many aspects of cellular metabolism, 25 proliferation, differentiation and development.

In a GSK-3 mediated pathway that is relevant for the treatment of type II diabetes, insulin-induced signaling leads to cellular glucose uptake and glycogen synthesis. Along this pathway, GSK-3 is a negative regulator of the insulin-induced signal. Normally, the presence of insulin causes inhibition of GSK-3 mediated phosphorylation and deactivation of glycogen synthase. The inhibition of GSK-3 leads to increased glycogen synthesis and glucose uptake [Klein et al., PNAS, 93,

30

8455-9 (1996); Cross et al., Biochem. J., 303, 21-26 (1994); Cohen, Biochem. Soc. Trans., 21, 555-567 (1993); Massillon et al., Biochem J. 299, 123-128 (1994)]. However, in a diabetic patient where the insulin response is impaired, glycogen synthesis and glucose uptake fail 5 to increase despite the presence of relatively high blood levels of insulin. This leads to abnormally high blood levels of glucose with acute and long term effects that may ultimately result in cardiovascular disease, renal failure and blindness. In such patients, the normal 10 insulin-induced inhibition of GSK-3 fails to occur. has also been reported that in patients with type II diabetes, GSK-3 is overexpressed [WO 00/38675]. Therapeutic inhibitors of GSK-3 are therefore potentially 15 useful for treating diabetic patients suffering from an impaired response to insulin.

GSK-3 activity has also been associated with Alzheimer's disease. This disease is characterized by the well-known β -amyloid peptide and the formation of 20 intracellular neurofibrillary tangles. neurofibrillary tangles contain hyperphosphorylated Tau protein where Tau is phosphorylated on abnormal sites. GSK-3 has been shown to phosphorylate these abnormal sites in cell and animal models. Furthermore, inhibition of GSK-3 has been shown to prevent hyperphosphorylation 25 of Tau in cells [Lovestone et al., Current Biology 4, 1077-86 (1994); Brownlees et al., Neuroreport 8, 3251-55 (1997)]. Therefore, it is believed that GSK-3 activity may promote generation of the neurofibrillary tangles and the progression of Alzheimer's disease. 30

Another substrate of GSK-3 is β -catenin which is degradated after phosphorylation by GSK-3. Reduced levels of β -catenin have been reported in schizophrenic patients and have also been associated with other

diseases related to increase in neuronal cell death [Zhong et al., Nature, 395, 698-702 (1998); Takashima et al., PNAS, 90, 7789-93 (1993); Pei et al., J. Neuropathol. Exp, 56, 70-78 (1997)].

- As a result of the biological importance of GSK-3, there is current interest in therapeutically effective GSK-3 inhbitors. Small molecules that inhibit GSK-3 have recently been reported [WO 99/65897 (Chiron) and WO 00/38675 (SmithKline Beecham)].
- 10 For many of the aforementioned diseases associated with abnormal GSK-3 activity, other protein kinases have also been targeted for treating the same diseases. However, the various protein kinases often act through different biological pathways. For example, 15 certain quinazoline derivatives have been reported recently as inhibitors of p38 kinase (WO 00/12497 to Scios). The compounds are reported to be useful for treating conditions characterized by enhanced $p38-\alpha$ activity and/or enhanced TGF- β activity. While p38 20 activity has been implicated in a wide variety of diseases, including diabetes, p38 kinase is not reported to be a constituent of an insulin signaling pathway that regulates glycogen synthesis or glucose uptake. Therefore, unlike GSK-3, p38 inhibition would not be 25 expected to enhance glycogen synthesis and/or glucose uptake.

There is a continued need to find new therapeutic agents to treat human diseases. The protein kinases aurora-2 and GSK-3 are especially attractive targets for the discovery of new therapeutics due to their important role in cancer, diabetes, Alzheimer's disease and other diseases.

20 products may be obtained by such quaternization.

The amount of the protein kinase inhibitor that may be combined with the carrier materials to produce a single dosage form will vary depending upon the patient treated and the particular mode of administration.

25 Preferably, the compositions should be formulated so that a dosage of between 0.01 - 100 mg/kg body weight/day of the inhibitor can be administered to a patient receiving these compositions.

It should also be understood that a specific

dosage and treatment regimen for any particular patient will depend upon a variety of factors, including the activity of the specific compound employed, the age, body weight, general health, sex, diet, time of administration, rate of excretion, drug combination, and

the judgment of the treating physician and the severity of the particular disease being treated. The amount of the inhibitor will also depend upon the particular compound in the composition.

Depending upon the particular protein kinasemediated condition to be treated or prevented, additional
therapeutic agents, which are normally administered to
treat or prevent that condition, may be administered
together with the inhibitors of this invention. For

example, in the treatment of diabetes other anti-diabetic
agents may be combined with the GSK-3 inhibitors of this
invention to treat diabetes. These agents include,

Those additional agents may be administered separately from the protein kinase inhibitor-containing composition, as part of a multiple dosage regimen.

10 Alternatively, those agents may be part of a single dosage form, mixed together with the protein kinase inhibitor of this invention in a single composition.

Compounds of this invention may exist in alternative tautomeric forms, as in tautomers 1 and 2 shown below. Unless otherwise indicated, the representation of either tautomer is meant to include the other.

General Synthetic Methods

10

15

20

25

30

The general synthetic methods below provide a series of general reaction routes that were used to

prepare compounds of this invention. Methods A-F below are particularly useful for preparing formula II compounds. In most cases, Ring C is drawn as a phenyl ring bearing an ortho R¹ substituent. However, it will be apparent to one skilled in the art that compounds having other Ring C groups may be obtained in a similar manner. Methods analogous to methods A-F are also useful for preparing other compounds of this invention. Methods F-I below are particulary useful for preparing compounds of formula III or IV.

Method A

5

10

15 Method A is a general route for the preparation of compounds wherein ring C is an aryl or heteroaryl Preparation of the starting dichloropyrimidine 1 may be achieved in a manner similar to that described in Chem. Pharm. Bull., 30, 9, 1982, 3121-3124. The chlorine 20 in position 4 of intermediate 1 may be replaced by an aminopyrazole or aminoindazole to provide intermediate 2 in a manner similar to that described in J. Med. Chem., 38, 3547-3557 (1995). Ring C is then introduced using a boronic ester under palladium catalysis (see Tetrahedron, 25 48, 37, 1992, 8117-8126). This method is illustrated by the following procedure.

A suspension of 1H-quinazoline-2,4-dione (10.0 g, 61.7 mmol) in $POCl_3$ (60 mL, 644 mmol) and N,N-dimethylaniline (8mL, 63.1 mmol) is heated under reflux

for 2 h. Excess POCl₃ is evaporated under vacuum, the residue is poured into ice, and the precipitate is collected by filtration. The crude solid 2,4-dichloroquinazoline product may be used without further purification.

To a solution of 2,4-dichloro-quinazoline (3.3 g, 16.6 mmol) in anhydrous ethanol (150 mL) is added 5-methyl-1H-pyrazol-3-yl amine (3.2 g, 32.9 mmol). The mixture is stirred at room temperature for 4 h, and the resulting precipitate is collected by filtration, washed with ethanol, and dried under vacuum to afford (2-chloro-quinazolin-4-yl)-(5-methyl-1H-pyrazol-3-yl)-amine.

To a solution of (2-chloro-quinazolin-4-yl)-(5-methyl-1H-pyrazol-3-yl)-amine (50 mg, 0.19 mmol) in DMF

(1.0 mL) is added the desired arylboronic acid (0.38 mmol), 2M Na2CO3 (0.96 mmol), and tri-t-butylphosphine (0.19 mmol). Under nitrogen, PdCl₂(dppf) (0.011 mmol) is added in one portion. The reaction mixture is then heated at 80°C for 5 to 10 hours, cooled to room

temperature, and poured into water (2 mL). The resulting precipitate is collected by filtration, washed with water, and purified by HPLC.

Method B

(ii)

5

10

Methods B through F describe routes where the 5 pyrazole ring system is introduced after Ring C and the pyrimidine ring portion are first constructed. A versatile intermediate is the 4-chloropyrimidine 4, which is readily obtained from pyrimidinone 3 as shown in Method B(i). This reaction sequence is generally applicable for a variety of Ring C groups including 10 aliphatic, aryl, heteroaryl, or heterocyclyl. See J. Med. Chem., 38, 3547-3557 (1995).

For quinazoline ring systems (where Rx and Ry are taken together to form a benzo ring), the useful 15 intermediate 6 may be obtained by condensing an anthranilic acid or its derivative with a benzamidine as shown in Method B(ii) or by condensing a benzoylchloride with an anthranilamide as shown in Method B(iii). substituted anthranilic acid, anthranilamide, benzamidine and benzoylchloride starting materials may be obtained by known methods. See Aust. J. Chem., 38, 467-474 and J. Med. Chem., 38, 3547-3557 (1995). Method B(iii) is illustrated by the following procedure.

20

To a solution of anthranilamide (33 mmol) in 25 THF and CH₂Cl₂ (1:1, 70 mL) is added the desired benzoylchloride (33 mmol), and triethylamine (99 mmol) at room temperature. The mixture is stirred for about 14 hours. The resulting precipitate is collected by filtration, washed with CH_2Cl_2 and water, and dried under 30 The crude 2-benzoylaminobenzamide may be used vacuum. directly for the next step without further purification.

To a solution of the above crude product (13 mmol) in ethanol (50 mL) is added NaOEt (26 mmol) at room temperature. The mixture is heated under reflux for 48 to 96 h. The solvent is evaporated and the residue is neutralized using concentrated HCl to pH 7. The product is then collected by filtration and dried under vacuum to provide 2-phenyl-3H-quinazolin-4-one that may be used without further purification.

To a suspension of the above product (12 mmol)
in POCl₃ (120 mmol) is added tri-n-propylamine (24 mmol).
The mixture is heated under reflux for 1h. After removal of the excess POCl₃ by evaporation, the residue is dissolved in ethyl acetate, and washed with 1N NaOH (twice) and water (twice). The organic layer is dried over MgSO₄, the solvent is evaporated under vacuum, and the crude product is purified by flash chromatography (eluting with 10% of ethyl actetate in hexanes) to give 4-chloro-2-aryl quinazoline.

To a solution of 4-chloro-2-aryl quinazoline

(0.16 mmol) in DMF (or THF, ethanol) (1 mL) is added the desired aminopyrazole or aminoindazole (0.32 mmol). The mixture is heated in DMF (or THF under reflux) at 100 to 110°C for 16 h (or in ethanol at 130-160°C for 16 hours) and then poured into water (2 mL). The precipitate is collected by filtration and purified by HPLC.

Method C

5

Method D(i)

15

20

25

30

Methods C and D(i) above employ β -ketoesters 8 and 10, respectively, as pyrimidinone precursors. The substitution pattern of the R^x and R^y groups on the pyrimidinone ring will be reversed if a chlorocrotonate 11 (Synth. Comm, (1986), 997-1002), instead of the corresponding β -ketoester 10, is condensed with the desired benzamidine. These methods are illustrated by the following general procedure.

To a solution of a β -ketoester (5.2 mmol) and amidinium chloride (5.7 mmol) in ethanol (5 mL) is added sodium ethoxide (7.8 mmol). The mixture is heated under reflux for 7-14 hours. After evaporation the resulting residue is dissolved in water, acidified with concentrated HCl to pH 6, and then filtered to obtain a solid product 2-aryl-3H-pyrimidin-4-one (yield 75-87%), which may be purified by flash column chromatography if needed. To this pyrimidinone (3.7 mmol) is added POCl₃ (4 mL) and $n-Pr_3N$ (1.4 mL). The mixture is heated under reflux for 1 hour. After evaporation of the excess POCl3, the residue is dissolved in ethyl acetate, washed with 1N NaOH solution (three times) and NaHCO3 (once), and dried over MgSO₄. The solvent is removed under vacuum and the residue is purified by flash column chromatography eluting with 10% of ethyl acetate in hexanes to give 2aryl-4-chloro-pyrimidine as a pale yellow syrup. crude product may be treated with a 3-aminopyrazole or 3aminoindazole as described above.

Method D(ii)

5

10

15

20

Method D(ii) above shows a general route for the preparation of the present compounds, such as compound 40, wherein R^{y} is $N(R^{4})_{2}$. See Il Farmaco, 52(1) 61-65 (1997). Displacement of the 6-chloro group is exemplified here using morpholine. This method is illustrated by the following procedure.

To a solution of 2-methylmalonic acid diethyl ester (5 mmol) and sodium ethoxide (15 mmol) is added the appropriate amidine salt (5 mmol) in ethanol (10 mL) and the reaction heated at reflux for 2-24 hours. The residue is dissolved in water and acidified with 2N HCl. The resulting precipitate is filtered off and further purified by flash chromatography (yield 5-35%) to afford the pyrimidinedione 37. To 37 (1.6 mmol) is added POCl₃ (32 mmol) and tri-n-propylamine (6.4 mmol) and the reaction refluxed is for 1h. After evaporation of excess POCl₃, the residue is dissolved in ethyl acetate, basified with 1N NaOH, separated and the aqueous phase twice more extracted with ethyl acetate. The combined organics are dried (sodium sulfate) and evaporated. Purification by

flash chromatography provides the dichloropyrimidine (38) as a yellow oil in 23% yield.

A solution of 38 (0.33 mmol) in methanol (5 mL) is treated with an amine, exemplified here using

5 morpholine (0.64 mmol) and refluxed 1 hour. After evaporation of solvent, the residue is purified by flash chromatography to provide the mono-chloropyrimidine 39 as a colorless oil in 75% yield.

The mono-chloropyrimidine, 39, (0.19 mmol) may

10 be treated with a 3-aminopyrazole or 3-aminoindazole

compound in a manner substantially similar those

described above in Methods A and B.

Method E

15

20

25

30

As shown by Method E, an acyl isocyanate 12 may be condensed with an enamine to provide pyrimidinone 9 (J. Org. Chem (1993), 58, 414-418; J.Med.Chem., (1992), 35, 1515-1520; J.Org.Chem., 91967, 32, 313-214). This method is illustrated by the following general procedure.

The enamine is prepared according to W. White,

et al, J. Org Chem. (1967), 32, 213-214. The acyl isocyanate is prepared according to G Bradley, et al, J Med. Chem. (1992), 35, 1515-1520. The coupling reaction then follows the procedure of S Kawamura, et al, J. Org. Chem, (1993), 58, 414-418. To the enamine (10 mmol) in tetrahydrofuran (30 mL) at 0°C under nitrogen is added dropwise over 5 min a solution of acyl isocyanate (10 mmol) in tetrahydrofuran (5 mL). After stirring for 0.5 h, acetic acid (30 mL) is added, followed by ammonium

acetate (50 mmol). The mixture is refluxed for 2 h with continuous removal of tetrahydrofuran. The reaction is cooled to room temperature and is poured into water (100 mL). The precipitate is filtered, washed with water and ether and dried to provide the 2-aryl-3H-pyrimidin-4-one.

Method F

5

25

30

Method F shows a general route for the preparation of the present compounds wherein R^x and R^y are taken together to form a 5-8 membered partially unsaturated saturated or unsaturated ring having 1-3 heteroatoms. The condensation of a 2-amino-carboxylic acid, such as 2-amino-nicotinic acid 13, and an acid chloride 7 provides an oxazinone 14. Treatment of 14 with ammonium hydroxide will furnish the benzamide 15 which may be cyclized to a 2-(substituted)-pyrido[2,3-d][1,3]pyrimidin-4-one 16. This method is illustrated by the following procedure.

2-(Trifluoromethyl)benzoyl chloride (4.2 ml, 29.2 mmol) is added dropwise to a solution of 2-aminonicotinic acid (2.04g, 14.76 mmol) in 20 ml of pyridine. The reaction mixture is heated at 158 C for 30 min then cooled to room temperature. The reaction is poured into 200 ml of water and an oil forms which solidifies upon stirring. The solid is collected by vacuum filtration and washed with water and diethyl ether. The product is dried to give 2-(2-

-231-

trifluoromethyl-phenyl)-pyrido[2,3-d][1,3]oxazin-4-one

(2.56 g, 60% yield) which may be used in the next step without further purification.

2-(2-Trifluoromethyl-phenyl)-pyrido[2,3-d][1,3]oxazin-4-one (2.51g) is stirred in 30% ammonium hydroxide (25 ml) at room temperature overnight. The resulting precipitate is filtered and rinsed with water and diethyl ether. The precipitate is dried under vacuum at 50 C overnight to give 2-(2-trifluoromethyl-benzoylamino)-nicotinamide (850 mg, 33% yield)

2-(2-Trifluoromethyl-benzoylamino)-nicotinamide (800mg, 2.6mmol) is dissolved in 10ml of ethanol.

Potassium ethoxide (435mg, 5.2mmol) is added to the solution which is heated to reflux for 16 h. The reaction mixture is evaporated in vacuo to afford a gummy residue that is dissolved in water and acidified with 10% sodium hydrogen sulfate to pH 7. The resulting precipitate is filtered and dried under vacuum at 50 C to give 2-(2-trifluoromethyl-phenyl)-3H-pyrido[2,3-d]pyrimidin-4-one.

20

5

Method G

Method G is analogous to Method B(i) above. This method is illustrated by the following general procedure.

2-(3,4-Dichloro-phenyl)-3H-quinazolin-4-one
(1g, 3.43 mmol) is suspended in phosphorus oxychloride (4 mL) and the reaction mixture was stirred at 110°C for 3 hours. The solvents are then evaporated and the residue is treated carefully with an ice cold aqueous saturated solution of NaHCO₃. The solid is collected by filtration and washed with ether to give 4-chloro-2-(3,5-dichloro-phenyl)-quinazoline as a white solid (993 mg, 93%).

To 4-chloro-2-(3,5-dichloro-phenyl)-quinazoline (400mg, 1.29 mmol) in THF (30 mL) is added 3-amino-5-

methyl pyrazole (396 mg, 2.58 mmol) and the reaction mixture is heated at 65°C overnight. The solvents are then evaporated and the residue triturated with ethyl acetate, filtered and washed with a minimum amount of ethanol to give [2-(3,4-dichlorophenyl)-quinazolin-4-yl]-(5-methyl-2H-pyrazol-3-yl)-amine as a white solid (311 mg 65%): mp 274°C; ¹H NMR (DMSO) δ 2.34 (3H, s), 6.69 (1H, s), 7.60 (1H, m), 7.84 (1H, d), 7.96 (2H, d), 8.39 (1H, dd), 8.60 (1H, d), 8.65 (1H, d), 10.51 (1H, s), 12.30 (1H, s); IR (solid) 1619, 1600, 1559, 1528, 1476, 1449, 1376, 1352, 797, 764, 738; MS 370.5 (M+H) $^+$.

The THF solvent used in the previous step may be replaced by other organic solvents such as ethanol, N,N-dimethylformamide, or dioxane.

Method I above shows a general route for the preparation of the present compounds wherein ring D is a heteroaryl or heterocyclyl ring directly attached to the pyrimidine 2-position via a nitrogen atom. Displacement of the 2-chloro group, exemplified here using piperidine, may be carried out in a manner similar to that described in J. Med. Chem., 38, 2763-2773 (1995) and J. Chem. Soc., 1766-1771 (1948). This method is illustrated by the following procedure.

To a solution of (2-chloro-quinazolin-4-yl)-(1H-indazol-3-yl)-amine (1 equivalent, 0.1-0.2 mmol) in N, N-dimethylacetamide (1 ml) is added the desired amine (3 equivalents). The resulting mixture is maintained at 100°C for 6 h and then purified by reverse-phase HPLC.

Method J

25

Method J above shows the preparation of 5 compounds of formula V via the displacement of a chloro group from an appropriately substituted pyridyl ring. Method J(i) is a route for preparing compounds of formula Va (see Indian J. Chem. Sect.B, 35, 8, 1996, 871-873). Method J(ii) is a route for preparing compounds of 10 formula Vb (see Bioorg. Med. Chem., 6, 12, 1998, 2449-2458). For convenience, the chloropyridines 21 and 23 are shown with a phenyl substituent corresponding to Ring D of formula V. It would be apparent to one skilled in the art that Method J is also useful for preparing 15 compounds of formula V wherein Ring D is heteroaryl, heterocyclyl, carbocyclyl or other aryl rings. Method J is illustrated by the following procedures.

Method J(i). (5-Methyl-2H-pyrazol-3-yl)-(2phenyl-quinolin-4-yl)-amine. To 4-chloro-220 phenylquinoline (J. Het. Chem., 20, 1983, 121-128)(0.53g,
2.21 mmol) in diphenylether (5 mL) was added 3-amino-5methylpyrazole (0.43g, 4.42 mmol) and the mixture was
heated at 200°C overnight with stirring. To the cooled
mixture was added petroleum ether (20 mL) and the
25 resulting crude precipitate was filtered and further
washed with petroleum ether. The crude solid was purified
by flash chromatography (SiO₂, gradient DCM-MeOH) to give
the title compound as a white solid: mp 242-244°C; ¹H NMR

To 1-chloro-3phenylisoquinoline (J. Het. Chem., 20, 1983, 121-5 128) (0.33g, 1.37 mmol) in dry DMF (5 mL) was added 3amino-5-methylpyrazole (0.27g, 2.74 mmol) and potassium carbonate (0.57g, 4.13 mmol) and the mixture was heated under reflux for 6 hours. The mixture was cooled and the 10 bulk of DMF was evaporated. The residue was extracted twice with ethyl acetate and the combined organic layers were washed with brine, dried (MgSO₄), filtered and concentrated. The crude was purified by flash chromatography (SiO₂, gradient DCM-MeOH) to give the title 15 compound as a colourless oil; ^{1}H NMR (MeOD) δ 2.23 (3H, s), 5.61 (1H, s), 7.41 (1H, m), 7.52(2H, m), 7.62(1H, m), 7.81(1H, m), 8.07(1H, d), 8.19(2H, m), 8.29(1H, s), 8.54

20 Method K

(1H, d); MS 301.2 (M+H)⁺

Method K shows a route for the preparation of compounds of formula VI. A versatile starting material is 2,4,6-trichloro-[1,3,5]triazine 25 in which the chlorine substituents may be sequentially displaced. The displacement of one of the chlorines by an aryl Grignard reagent or an aryl boronic acid is described in PCT patent application WO 01/25220 and Helv. Chim. Acta, 33, 1365 (1950). The displacement of one of the chlorines by a heteroaryl ring is described in WO 01/25220; J. Het.

Chem., 11, 417 (1974); and Tetrahedron 31, 1879 (1975). These reactions provide a 2,4-dichloro-(6-substituted) [1,3,5] triazine 26 that is a useful intermediate for the preparation of compounds of formula VI. Alternatively, intermediate 26 may be obtained by constructing the triazine ring by known methods. See US patent 2,832,779; and US patent 2,691020 together with J. Am. Chem. Soc. 60, 1656 (1938). In turn, one of the chlorines of 26 may be displaced as described above to provide 2-chloro-(4,6-disubstituted) [1,3,5] triazine 27. The treatment of 27 with an appropriate aminopyrazole provides the desired compound of formula VI.

Method L shows a route for preparing compounds of formula VII. For illustration purposes the trifluoromethylchalcone 28 is used as a starting material; however, it would be apparent to one skilled in the art that other rings may be used in place of the

trifluoromethylphenyl and phenyl rings of compound 28. Substituted chalcones may be prepared by known methods. for example as described in the Indian J. Chemistry, 32B, 449 (1993). Condensation of a chalcone with urea provides the pyrimidinone 29, which may be treated with 5 POCl₃ to give the chloropyrimidine 30. See J. Chem. Eng. Data, 30(4) 512 (1985) and Egypt. J. Chem., 37(3), 283 (1994). In an alternative approach to compound 30, one of the aryl rings attached to the pyrimidine is 10 introduced by displacement of of the 4-chloro group of 2,4-dichloro-(6-aryl)-pyrimidine by an aryl boronic acid using a palladium catalyst such as (Ph3P)4Pd in the presence of a base such as sodium carbonate as described in Bioorg. Med. Lett., 9(7), 1057 (1999). Displacement 15 of the chlorine of compound 30 by an appropriate aminopyrazole provides compounds of this invention, such The last step of this method is illustrated by

To a solution of 2-20 chloro-4-(4-methylpiperidin-1-yl)-pyrimidine (prepared using a procedure similar to the one reported in Eur. J. Med. Chem., 26(7) 729(1991))(222 mg, 1.05 mmol) in BuOH (5 mL) was added 3-amino-5-methyl-2H-pyrazole (305mg, 25 3.15 mmol) and the reaction mixture was then heated under reflux overnight. The solvent was evaporated and the residue dissolved in a mixture ethanol/water (1/3, 4 mL). Potassium carbonate (57mg, 0.41 mmol) was added and the mixture was stirred at room temperature for 2 hours. The 30 resulting suspension was filtered, washed with water twice and rinsed with ether twice to give the title compound as a white solid (143mg, 50%): mp 193-195°C; ¹H NMR (DMSO) δ 0.91 (3H, d), 1.04 (2H, m), 1.67 (3H, m), 2.16 (3H, s), 2.83 (2H, t), 4.31 (2H, m), 6.19 (2H, m),

5 Method M

Method M provides routes for obtaining

20 compounds of formula VIII. A general procedure for displacing the chlorine of a 4-chloro-6-substituted-pyridazine, 32, with an appropriately substituted

pyrazole to provide VIIIa is described in J. Het. Chem., 20, 1473 (1983). Analogous reactions may be carried out as follows: (a) with 3-chloro-5-substituted-pyridazine, 33, to provide VIIIb is described in J. Med. Chem., 41(3), 311 (1998); (b) with 5-chloro-3-substituted-[1,2,4]triazine, 34, to provide VIIIc is described in Heterocycles, 26(12), 3259 (1987); and (c) with 3-chloro-5-substituted-[1,2,4]triazine, 35, to provide VIIId is described in Pol. J. Chem., 57, 7, (1983); Indian J. Chem. Sect. B, 26, 496 (1987); and Agric. Biol. Chem., 54(12), 3367 (1990). An alternative procedure to

Chem. Sect. B, 26, 496 (1987); and Agric. Biol. Chem., 54(12), 3367 (1990). An alternative procedure to compounds of formula VIIIc is described in Indian J. Chem. Sect. B, 29(5), 435 (1990).

BIOLOGICAL TESTING

The activity of the compounds as protein kinase inhibitors may be assayed in vitro, in vivo or in a cell 15 In vitro assays include assays that determine inhibition of either the phosphorylation activity or ATPase activity of the activated protein kinase. Alternate in vitro assays quantitate the ability of the inhibitor to bind to the protein kinase. Inhibitor 20 binding may be measured by radiolabelling the inhibitor prior to binding, isolating the inhibitor/protein kinase complex and determining the amount of radiolabel bound. Alternatively, inhibitor binding may be determined by running a competition experiment where new inhibitors are 25 incubated with the protein kinase bound to known radioligands.

BIOLOGICAL TESTING EXAMPLE 1

K_i DETERMINATION FOR THE INHIBITION OF GSK-3

Compounds were screened for their ability to inhibit GSK-3β (AA 1-420) activity using a standard coupled enzyme system (Fox et al. (1998) Protein Sci. 7, 2249). Reactions were carried out in a solution containing 100 mM HEPES (pH 7.5), 10 mM MgCl₂, 25 mM NaCl,

300 μ M NADH, 1 mM DTT and 1.5% DMSO. Final substrate concentrations in the assay were 20 μ M ATP (Sigma Chemicals, St Louis, MO) and 300 μ M peptide (HSSPHQS(PO₃H₂)EDEEE, American Peptide, Sunnyvale, CA).

- 5 Reactions were carried out at 30 °C and 20 nM GSK-3β. Final concentrations of the components of the coupled enzyme system were 2.5 mM phosphoenolpyruvate, 300 μM NADH, 30 μg/ml pyruvate kinase and 10 μg/ml lactate dehydrogenase.
- 10 An assay stock buffer solution was prepared containing all of the reagents listed above with the exception of ATP and the test compound of interest. The assay stock buffer solution (175 μ l) was incubated in a 96 well plate with 5 μl of the test compound of interest at final concentrations spanning 0.002 μM to 30 μM at 30 . 15 °C for 10 min. Typically, a 12 point titration was conducted by preparing serial dilutions (from 10 mM compound stocks) with DMSO of the test compounds in daughter plates. The reaction was initiated by the 20 addition of 20 μ l of ATP (final concentration 20 μ M). Rates of reaction were obtained using a Molecular Devices Spectramax plate reader (Sunnyvale, CA) over 10 min at 30 The K_i values were determined from the rate data as a function of inhibitor concentration.

BIOLOGICAL TESTING EXAMPLE 6 SRC INHIBITION ASSAY

The compounds were evaluated as inhibitors of human Src kinase using either a radioactivity-based assay or spectrophotometric assay.

Src Inhibition Assay A: Radioactivity-based Assay

The compounds were assayed as inhibitors of full length recombinant human Src kinase (from Upstate Biotechnology, cat. no. 14-117) expressed and purified from baculo viral cells. Src kinase activity was monitored by following the incorporation of ³³P from ATP into the tyrosine of a random poly Glu-Tyr polymer substrate of composition, Glu:Tyr = 4:1 (Sigma, cat. no.

The following were the final concentrations of the assay components: 0.05 M HEPES, pH 7.6, 10 mM MgCl2, 2 mM DTT, 0.25 mg/ml BSA, 10 μ M ATP (1-2 μ Ci 33 P-ATP per reaction), 5 mg/ml poly Glu-Tyr, and 1-2 units of 5 recombinant human Src kinase. In a typical assay, all the reaction components with the exception of ATP were pre-mixed and aliquoted into assay plate wells. Inhibitors dissolved in DMSO were added to the wells to give a final DMSO concentration of 2.5%. The assay plate 10 was incubated at 30 °C for 10 min before initiating the reaction with ³³P-ATP. After 20 min of reaction, the reactions were quenched with 150 µl of 10% trichloroacetic acid (TCA) containing 20 mM Na₃PO₄. The quenched samples were then transferred to a 96-well filter plate (Whatman, UNI-Filter GF/F Glass Fiber 15 Filter, cat no. 7700-3310) installed on a filter plate vacuum manifold. Filter plates were washed four times with 10% TCA containing 20 mM Na₃PO₄ and then 4 times with methanol. 200µl of scintillation fluid was then added to 20 each well. The plates were sealed and the amount of radioactivity associated with the filters was quantified on a TopCount scintillation counter. The radioactivity incorporated was plotted as a function of the inhibitor concentration. The data was fitted to a competitive 25 inhibition kinetics model to get the Ki for the compound.

Src Inhibition Assay B: Spectrophotometric Assay

The ADP produced from ATP by the human recombinant Src kinase-catalyzed phosphorylation of poly Glu-Tyr substrate was quanitified using a coupled enzyme assay (Fox et al (1998) Protein Sci 7, 2249). In this assay one molecule of NADH is oxidised to NAD for every molecule of ADP produced in the kinase reaction. The

30

disappearance of NADH can be conveniently followed at 340 nm.

The following were the final concentrations of the assay components: 0.025 M HEPES, pH 7.6, 10 mM MgCl2, 2 mM DTT, 0.25 mg/ml poly Glu-Tyr, and 25 nM of recombinant human Src kinase. Final concentrations of the components of the coupled enzyme system were 2.5 mM phosphoenolpyruvate, 200 µM NADH, 30 µg/ml pyruvate kinase and 10 µg/ml lactate dehydrogenase.

- In a typical assay, all the reaction components with the exception of ATP were pre-mixed and aliquoted into assay plate wells. Inhibitors dissolved in DMSO were added to the wells to give a final DMSO concentration of 2.5%. The assay plate was incubated at 30°C for 10 min before initiating the reaction with 100 µM ATP. The absorbance change at 340 nm with time, the rate of the reaction, was monitored on a molecular devices plate reader. The data of rate as a function of the inhibitor concentration was fitted to compettive inhibition
- 20 kinetics model to get the K_i for the compound.
